

where  $h_c$  = heat-transfer coefficient by convection,  $\text{J}/(\text{m}^2 \cdot \text{s} \cdot \text{K})$  [ $\text{Btu}/(\text{h} \cdot \text{ft}^2 \cdot ^\circ\text{F})$ ];  $t$  = air temperature,  $\text{K}$ ;  $t_w$  = wet-bulb temperature of air,  $\text{K}$ ;  $k'_g$  = mass-transfer coefficient,  $\text{kg}/(\text{s} \cdot \text{m}^2)$  [ $\text{kg}/\text{kg}$ ] [ $\text{lb}/(\text{h} \cdot \text{ft}^2)(\text{lb}/\text{lb})$ ];  $\lambda$  = latent heat of evaporation at  $t_w$ ,  $\text{J}/\text{kg}$  ( $\text{Btu}/\text{lb}$ );  $H_w$  = saturated humidity at  $t_w$  =  $\text{kg}/\text{kg}$  of dry air; and  $H_a$  = humidity of the surrounding air,  $\text{kg}/\text{kg}$  of dry air.

For air–water–vapor mixtures, it so happens that  $h_c/k'_g = C_s$ , approximately, although there is no theoretical reason for this. Hence, since the ratio  $(H_w - H_a)/(t_w - t)$  equals  $h_c/k'_g/\lambda$ , which represents the slope of the wet-bulb-temperature lines, it is also equal to  $C_s/\lambda$ , the slope of the adiabatic-saturation lines as shown previously.

A given humidity chart is precise only at the pressure for which it is evaluated. Most air–water–vapor charts are based on a pressure of 1 atm. Humidities read from these charts for given values of wet- and dry-bulb temperature apply only at an atmospheric pressure of 760 mmHg. If the total pressure is different from 760 mmHg, the humidity at a given wet-bulb and dry-bulb temperature must be corrected according to the following relationship.

$$H_a = H_o + 0.622 p_w \left( \frac{1}{P - p_w} - \frac{1}{760 - p_w} \right) \quad (12-23)$$

where  $H_a$  = humidity of air at pressure  $P$ ,  $\text{kg}/\text{kg}$  of dry air;  $H_o$  = humidity of air as read from a humidity chart based on 760-mm pressure at the observed wet- and dry-bulb temperatures,  $\text{kg}/\text{kg}$  dry air,  $p_w$  = vapor pressure of water at the observed wet-bulb temperature, mmHg; and  $P$  = the pressure at which the wet- and dry-bulb readings were taken. Similar corrections can be derived to correct specific volume, the saturation-humidity curve, and the relative-humidity curves.

## HUMIDITY CHARTS FOR SOLVENT VAPORS

Humidity charts for other solvent vapors may be prepared in an analogous manner. There is one important difference involved, however, in that the wet-bulb temperature differs considerably from the adiabatic-saturation temperatures for vapors other than water.

Figures 12-37 to 12-39 show humidity charts for carbon tetrachloride, benzene, and toluene. The lines on these charts have been calculated in the manner outlined for air–water vapor except for the wet-bulb-temperature lines. The determination of these lines depends on data for the psychrometric ratio  $h_c/k'_g$ , as indicated by Eq. (12-22). For the charts shown, the wet-bulb-temperature lines are based on the following equation:

$$H_w - H = (\alpha h_c / \lambda_w k'_g)(t - t_w) \quad (12-24)$$

where  $\alpha$  = radiation correction factor, a value of 1.06 having been used for these charts. Values of  $h_c/k'_g$ , obtained from values of  $h_c/k'_g C_s$  as presented by Walker, Lewis, McAdams, and Gilliland (*Principles of Chemical Engineering*, 3d ed., McGraw-Hill, New York, 1937), where  $C_s$  = humid heat of air with respect to the vapor involved, are as follows:

Material	Carbon tetrachloride	Benzene	Toluene
$h_c/k'_g C_s$	0.51	0.54	0.47

A discussion of the theory of the relationship between  $h_c$  and  $k'_g$  may be found in the psychrometry part of this section. Because both theoretical and experimental values of  $h_c/k'_g$  apply only to dilute gas mixtures, the wet-bulb lines at high concentrations have been omitted. For a discussion of the precautions to be taken in making psychrometric determinations of solvent vapors at low solvent wet-bulb temperatures in the presence of water vapor, see the paper by Sherwood and Comings [*Trans. Am. Inst. Chem. Eng.*, **28**, 88 (1932)].

## GENERAL CONDITIONS FOR DRYING

Solids drying encompasses two fundamental and simultaneous processes: (1) heat is transferred to evaporate liquid, and (2) mass is

FIG. 12-37 Humidity chart for air-carbon tetrachloride vapor mixture. To convert British thermal units per pound to joules per kilogram, multiply by 2326; to convert British thermal units per pound dry air-degree Fahrenheit to joules per kilogram-kelvin, multiply by 4186.8; and to convert cubic feet per pound to cubic meters per kilogram, multiply by 0.0624.
